DNA SEQUENCES FOR AN AMINO ACID TRANSPORTER,
PLASMIDS, BACTERIA, YEASTS AND PLANTS CONTAINING
A TRANSPORTER AND THEIR USE

Ins. A1 >

BACKGROUND OF THE INVENTION5 1. Field of the Invention:

10 The present invention relates to DNA sequences that contain the coding region of amino acid transporters, whose introduction in a plant genome modifies the transfer of metabolites in transgenic plants, plasmids, bacteria, yeasts and plants containing these DNA sequences, as well as their use.

15 For many plant species it is known that the delivery of energy-rich compounds to the phloem through the cell wall takes place throughout the cell. Transporter molecules which allow the penetration of amino acids through the plant cell wall are not known.

20 In bacteria, numerous amino acid transport systems have been characterized. For aromatic amino acids, 5 different transporters have been described which can transport any one of phenylalanine, tyrosine and tryptophan, while the other transporters are specific for individual amino acids (see Sarsero et al., 1991, J Bacteriol 173: 3231-3234). The speed constants of the transport process indicates that the specific transport is less efficient. For several transporter proteins, the
25 corresponding genes have been cloned. This has been achieved using transport-deficient mutants which were selected for their transport ability after transformation

with DNA fragments as inserts in expression vectors (see Wallace et al., 1990, J Bacteriol 172: 3214-3220). The mutants were selected depending on their ability to grow in the presence of toxic analogues of amino acids, since
5 the mutants cannot take these up and therefore cannot be impaired.

Corresponding complementation studies have been carried out with the eukaryotic yeast, *Saccharomyces cerevisiae*. Tanaka & Fink (1985, Gene 38: 205-214)
10 describe a histidine transporter that was identified by complementation of a mutation. Vandenbol et al. (1989, Gene 83: 153-159) describe a proline transporter for *Saccharomyces cerevisiae*. The yeast possesses two different permeases for proline. One transports with
15 lower efficiency and can be used also for other amino acids, and the other is proline-specific and works with high affinity. The latter was coded from the *put4* gene. This carries an open reading frame for a peptide with a molecular weight of 69 kDa. The protein contains 12
20 membrane-penetrating regions, but does not contain any N-terminal signal sequence for secretion. This is a typical property of integral membrane proteins. The permeases process homology for arginine and for histidine permease from yeast, but not, however, for proline
25 permease from *Escherichia coli*.

For plant cells, based on studies on tobacco suspension cultures, it has been found that the transport of arginine, asparagine, phenylalanine and histidine are pH and energy dependent. Since a 1,000-fold excess of
30 leucine inhibits the transport of the other amino acids, it can be assumed, therefore, that all amino acids use

the same transporter (McDaniel et al., 1982, Plant Physio
69: 246-249). Li and Bush (1991, Plant Physiol 96: 1338-
1344) determined, for aliphatic, neutral amino acids, two
5 transport systems in plasma membrane vesicles from *Beta*
vulgaris. On the one hand, alanine, methionine,
glutamine and leucine displace each other on the
transporter protein. On the other hand, isoleucine,
valine and threonine have mutually competitive effects.
In combined competition kinetic studies (Li & Bush, 1990,
10 Plant Physiol 94: 268-277) four different transport
systems have been distinguished. Besides a transporter
for all neutral amino acids, which work with low
affinity, there exists a high affinity type which,
however, possesses low affinity for isoleucine,
15 threonine, valine and proline. Further transporters
exist for acids as well as for basic amino acids.

The transporter molecule or gene for plant
transporter proteins is not known.

SUMMARY OF THE INVENTION

20 There are now described DNA sequences which
contain the coding region of a plant amino acid
transporter, and whose information contained in the
nucleotide sequence allows, by integration in a plant
genome, the formation of RNA, by which a new amino acid
25 transport activity can be introduced in the plant cells
or an endogenous amino acid transporter activity can be
expressed.

Under the term amino transporter is to be
understood, for example a cDNA sequence that codes an
30 amino transporter from *Arabidopsis thaliana*.

5 The identification of the coding region of the amino acid transporter is carried out by a process which allows the isolation of plant DNA sequences which code transporter molecules by means of expression in specific mutants of yeast *Saccharomyces cerevisiae*. For this, suitable yeast mutants have to be provided which cannot take up a substance for which the coding region of the transporter molecule has to be isolated from a plant gene library.

10 A mutant which cannot grow in media, with proline or citrulline as the only nitrogen source, is described by Jauniaux et al. (1987), Eur J Biochem 164: 601-606).

15 For the preparation of yeast strains that can be used to identify plant amino acid transporters, a yeast mutant which is not able to grow in media with proline and/or citrulline as the only nitrogen source is, for example, transformed with pFL 61 plasmid, which carries, as an insert, cDNA fragments from a cDNA library from *Arabidopsis thaliana*.

20 Further, a double mutant JT16 (Tanaka & Fink, 1985, Gene 38: 205-214) which has a deficiency in histidine synthesis (*his4*) and in histidine uptake (*hip1*) is transformed with the described pFL 61 plasmid and
25 cultivated in a medium with addition of histidine.

It has now surprisingly been found that, in the transformation of yeast cells, certain plant cDNA fragments can complement the yeast mutation. By analysis of the properties of the proteins coded from the cDNA it
30 can be shown that a coding region that codes a plant amino acid transporter with a wide specificity spectrum

is responsible for the complementing of the mutation (see example 3).

Such a coding region of an amino acid transporter is shown, for example, by one of the following nucleotide sequences:

5 The DNA sequences of the invention identified
 with the help of the transformed yeast strains, e.g.,
 sequences Seq. No. 1 and 2, can be introduced into
 plasmids and thereby be combined with steering elements
 for expression in eukaryotic cells (see Example 4).
 These steering elements are, on the one hand,
 transcription promoters, and, on the other hand,
 transcription terminators. Plasmids can be used to
 transform eukaryotic cells with the aim of expression of
 10 a translatable mRNA which makes possible the synthesis of
 an amino acid transporter in the cells or with the aim of
 expression of a non-translatable RNA, which prevents
 synthesis of an endogenous amino acid transporter in the
 cells. The expression of an RNA corresponding to the
 15 inventive sequences of plant amino acid transporters
 modifies the plant acid metabolism, as well as total
 nitrogen metabolism. The economic significance of this
 modification is obvious. Nitrogen is the nutrient mainly
 responsible for limiting growth. The viability of germ
 20 lines as well as germination capacity of seeds is
 directly dependent on the nitrogen content of storage
 tissue. The formation of high value food materials with
 a high protein content is dependent on a sufficient

09054774-051401

0985474 051401
T04750 424586

5 Nitrogen supply. Nitrogen is transported essentially in
the form of amino acids. An improvement in the delivery
of amino acids to their harvested parts can therefore
lead to an increase in yield of agricultural plants. The
possibility of forcing the uptake of amino acid in
individual organs allows the qualitative improvement of
such organs, which, because of the demands of the
utilization process, contain little nitrogen. An example
is potatoes which are grown for the production of starch.
10 Besides this, it is possible to modify the whole plant,
by which the growth of individual tissues, for example,
leaves, is slowed down, while the growth of the harvested
parts is increased. For this, one can imagine a
lengthening of the vegetative phase of crops, which leads
15 to an increased formation of storage substances.

Processes for the genetic modification of
dicotyledonous and monocotyledonous plants are already
known (see for example Gasser, C.S., Fraley, R.T., 1989,
Science 244: 1293-1299; Potrykus, 191, Ann Rev Plant Mol
20 Biol Plant Physiol 42: 205-225). For expression in
plants the coding sequences must be coupled with the
transcriptional regulatory elements. Such elements,
called promoters, are known (EP 375091).

Further, the coding regions must be provided
25 with transcription termination signals with which they
can be correctly transcribed. Such elements are also
described (see Gielen et al., 1989, EMBO J 8: 23-29).
The transcriptional start region can be either native
and/or homologous or foreign and/or heterologous to the
30 host plant. If desired, termination regions are
interchangeable with one another. The DNA sequence of

the transcription starting and termination regions can be prepared synthetically, obtained naturally, or can be a mixture of synthetic and natural DNA constituents. For introduction of foreign genes in higher plants, a large number of cloning vectors are available that include a replication signal for *E. coli* and a marker which allows for the selection of the transformed cells. Examples of such vectors are pBR 322, pUC-Series, M13 mp-Series, pACYC 184, etc. Depending on the method of introduction of the desired gene in the plants, other DNA sequences may be suitable. Should the Ti- or Ri-plasmid be used, e.g., for the transformation of the plant cell, then at least the right boundary, often, however, both the right and left boundary of the Ti- and Ri-Plasmid T-DNA, is attached, as a flanking region, to the gene being introduced. The use of T-DNA for the transformation of plant cells has been intensively researched and is well described in EP 120 516; Hoekama, In: The Binary Plant Vector System, Offset-drukkerij Kanthers B.V. Alblasserdam (1985), Chapter V; Fraley, et al., Crit. Rev. Plant Sci., 4:1-46 and An et al. (1985) EMBO J. 4: 277-287. Once the introduced DNA is integrate in the genome, it is generally stable there and remains in the offspring of the original transformed cells. It normally contains a selection marker which induces resistance in the transformed plant cells against a biocide or antibiotic such as kanamycin, G 418, bleomycin, hygromycin or phosphinotricin, etc. The individual marker employed should therefore allow the selection of transformed cells from cells which lack the introduced DNA.

For the introduction of DNA into a plant host cell, besides transformation using *Agrobacteria*, there are many other techniques available. These techniques include the fusion of protoplasts, microinjection of DNA and electroporation, as well as ballistic methods and virus infection. From the transformed plant material, whole plants can be regenerated in a suitable medium which contains antibiotics or biocides for selection. The resulting plants can then be tested for the presence of introduced DNA. No special demands are placed on the plasmids in injection and electroporation. Simple plasmids, such as, e.g., pUC-derivatives, can be used. Should whole plants be regenerated from such transformed cells, the presence of a selectable marker gene is necessary. The transformed cells grow within the plants in the usual manner (see also McCormick et al. (1986) Plant Cell Reports 5: 81-84). These plants can be grown normally and crossed with plants that possess the same transformed genes or different genes. The resulting hybrid individuals have the corresponding phenotypical properties.

The DNA sequences of the invention can also be introduced in plasmids and thereby combined with steering elements for an expression in prokaryotic cells. The formation of a translatable RNA sequence of a eukaryotic amino acid transporter from bacteria, in spite of the considerable differences in the membrane structures of prokaryotes and eukaryotes, means that prokaryotes can now use a eukaryotic amino acid transporter with specificity for certain substrates. This makes possible the production of bacterial strains which could be used

5

10

15

30

30

be cleaved and bound with another DNA sequence. Each plasmid sequence can be cloned in the same or different plasmids.

Derivatives or parts of the DNA sequences and plasmids of the invention can also be used for the transformation of prokaryotic and eukaryotic cells. Further, the DNA sequences of the invention can be used according to standard processes for the isolation of similar sequences on the genome of plants of various species, which also code for amino acid or other oligosaccharide transporter molecules. With these sequence constructs, for the transformation of plant cells, can be prepared which modify the transport process in transgenic plants.

In order to specify related DNA sequences, gene libraries must first be prepared which are representative of the content of genes of a plant type or for the expression of genes in a plant type. The former are genomic libraries, while the latter are cDNA libraries. From these, related sequences can be isolated using the DNA sequences of the invention as probes. Once the related gene has been identified and isolated, a determination of the sequence and an analysis of the properties of the proteins coded from this sequence is possible.

In order to understand the examples forming the basis of this invention all the processes necessary for these tests and which are known per se will first of all be listed:

1. Cloning process

For cloning in *E. coli*, the vector pBluescriptSK (Short et al., 1988, Nucl Acids Res 16: 7583-7600) was used.

5 For the transformation of yeasts, the vector pFL61 (Minet & Lacroute, 1990, Curr Genet 18: 287-291) was used.

For the plant transformation the gene constructs in the binary vector pBIN-Hyg were cloned.

2. Bacterial and yeast strains

10 For the pBluescriptSK vector as well as for PBinAR constructs, the *E. coli* strain XL1blue (Bullock et al., 1987, Biotechniques, 5, 376-378) was used.

15 As a starting strain for the expression of the cDNA library in yeast, the yeast strain 22574d (Jauniaux et al., 1987 Eur J Biochem 164: 601-606) was used.

The transformation of the plasmids in potato plants was carried out using *Agrobacterium tumefaciens* strain LBA4404 (Bevan (1984) Nucl. Acids Res 12: 8711-8720).

20 3. Transformation of *Agrobacterium tumefaciens*

The transfer of the DNA in *Agrobacteria* was carried out by direct transformation by the method of Höfgen & Willmitzer (1988, Nucleic Acids Res 16: 9877). The plasmid DNA of the transformed *Agrobacterium* was
25 isolated in accordance with the method of Birnboim and Doly (1979) (Nucl Acids Res 7: 1513-1523) and was analyzed by gel electrophoresis after suitable restriction cleavage.

4. Plant transformation

30 Ten small leaves, wounded with a scalpel, of a sterile potato culture were placed in 10 ml of MS medium

with 2% amino acid containing 30-50 μ l of an *Agrobacterium tumefaciens* overnight culture grown under selection. After 3-5 minutes of gentle shaking, the leaves were laid out on MS medium of 1.6% glucose, 2 mg/l of zeatin ribose, 0.02 mg/l of naphthylacetic acid, 0.02 mg/l of gibberellic acid, 500 mg/l of claforan, 50 mg/l of kanamycin and 0.8% bacto agar. After incubation for one week at 25°C and 3000 lux, the claforan concentration in the medium was reduced by half.

Deposits

The following plasmids and yeast strains were deposited at the Deutschen Sammlung von Mikroorganismen (DSM) in Braunschweig, Germany on 12.06.1992 (deposit number):

Plasmid pPPP1-20 (DSM 7129)
Plasmid pBinPPP1-20 (DSM 7130)

Other features and advantages of the present invention will become apparent from the following description of the invention which refers to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 shows the plasmid pPPP1-20 which contains the sequence Seq-ID No. 1. The finely drawn line corresponds to the sequence from pBluescriptSK. The thicker line represents the cDNA insert. The cleavage positions of the inserts are shown.

Fig. 2 shows the uptake of 14 C-proline from the medium.

no = time period of the uptake without competitor;

proline = time period with fourfold excess of
unlabeled proline;

citrulline = time period with fourfold excess
of unlabeled citrulline;

5 GABA = time period with fourfold excess of
gamma-aminobutyric acid;

time = time in seconds;

cpm = decays counted per minute.

5782
10 Fig. 3 shows the plasmid pAAP2 which contains
the sequence Seq-ID No. 2. The finely drawn line
corresponds to the sequence from pBluescriptSK. The
thicker line represents the cDNA insert. The cleavage
positions of the inserts are shown.

15 Fig. 4 shows a competition experiment with the
yeast line 22574d::AAP2. In this experiment, the uptake
of ^{14}C -labeled L-proline from the medium in the presence
of a fourfold excess of other amino acids or their
analogues is measured. Besides the standard
abbreviations for amino acids in the three letter code,
20 the following are also used:

Cit = citrulline;

D-Pro = D-proline;

OH-Pro = hydroxyproline; and

AC2 = azetidine-2-carboxylic acid.

25 Fig. 5 shows a competition experiment with the
yeast line JT16::AAP2. In this experiment, the uptake of
 ^{14}C labeled L-histidine from the medium in the presence of
a tenfold excess of other amino acids or their analogues
is measured.

Besides the standard abbreviations for amino acids in the three letter code, the following are also used:

5 Cit = citrulline;
Orn = ornithine;
Can = canavanine; and
NH4 = ammonium.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

10 The following examples describe the cloning and identification, as well as the function and use of a plant amino acid transporter.

Example 1

Cloning of the cDNA of a plant amino acid transporter

15 For complementation of the proline transport mutation of the yeast strain 22574d (Jauniaux et al., 1987, Eur J Biochem 164: 601-606) and/or the histidine synthesis and transport mutation of the strain JT16 (Tanaka & Fink 1985, Gene 38: 205-214), a cDNA of young germ lines from *Arabidopsis thaliana* (two leaf stage) in
20 the yeast expression vector pFL61 (Minet & Lacroute), 1990 Curr Genet 18: 287-291) which had been made available by Minet (Minet et al., 1992, Plant J 2: 417-422) was used. Around 1 µg of the vector with the cDNA-insert was transformed in the yeast strain 22574d and/or
25 JT16 by the method of Dohmen et al. (1991, Yeast 7: 691-692). Yeast transformands, which could grow in media with 4 mM proline as the sole nitrogen source or in media with 6 mM histidine, were propagated. From the lines plasmid-DNA was prepared by standard methods. Clones
30 that could complement the particular mutation contained

plasmids with similar restriction type of the cDNA insert. These varied in size between 1.6 and 1.7 kb.

Example 2

Sequence analysis of the cDNA insert of the plasmid pFL61-ppp1-20

5

From a yeast line PPP1-20, obtained in a similar manner to example 1, which, in spite of the 22574d mutation, could grow with proline as the only nitrogen source, the plasmid pFL61-ppp1-20 was isolated. Its cDNA insert was prepared as a NotI fragment and cloned in the vector pBluescriptSK. In this way, the plasmid pPPP1-20 was obtained (see Figure 1). Using synthetic oligonucleotides, the insert was sequenced by the method of Sanger et al. (1977, Proc Natl Acad Sci USA 74:5463-5467). The sequence is given above (SEQ ID No. 1).

10

15

20

25

~~In a similar way, from a yeast line that, in spite of the *his4/hip1* double mutation, could be grown in a medium with histidine addition, the plasmid pFL61-aap2 was isolated whose insert was also cloned as a NotI fragment in pBluescriptSK. The resulting plasmid pAAP2 was sequenced and the sequence (SEQ ID No. 2) is given above. The plasmid pAAP2 has a similar structure to pPPP1-20 (see Fig. 1), but instead of the insert SEQ ID No. 1, carries the insert SEQ ID No. 2 (see Fig. 3).~~

Example 3

Uptake studies with ^{14}C -labeled protein into the yeast line PPP1-20 and AAP2

5 The yeast lines 22574d::PPP1-20 and
22574d::AAP2 that were obtained in a similar manner to
Example 1 were grown in liquid medium until the culture
reached the logarithmic phase. After centrifuging the
culture, the cells are washed and taken up in 100 mM
10 tris/HCl pH 4.5, 2mM MgCl₂, and 0.6M sorbitol. Around 100
μL of the suspension was added to a solution of 0.5mM
L-proline plus 1 μCi ^{14}C labeled L-proline in 100 μL of
the same buffer. The uptake of the labeled amino acid
was measured by the process described by Cirillo (1989,
15 Meth Enzymol 174: 617-622). The uptake of the labeled
amino acid was compared, on the one hand, in co-
incubation with protein modifying substance diethyl
pyrocarbonate which is an inhibitor of the amino acid
transport in membrane vesicles from *Beta vulgaris*, and,
on the other hand, in co-incubation with other protein
20 modifying substances. The calculated reduction is shown
in Tables I and/or III. A competition experiment in
which the specificity of the transporter could be read
off with various amino acids and analogues is shown in
Table II for PPP1-20 and in Fig. 4 for AAP2. An
25 analogous experiment in which a competition for histidine
uptake in the line JT16::AAP2 was tested is described in
Example 5. The time period for PPP1-20 is shown in
Fig. 2.

Example 4

Transformation of plants with a construct for overexpression of the coding region of amino acid transporters

5 From the plasmid pPPP1-20 that contains the
cDNA for the amino acid transporter from *Arabidopsis*, an
internal fragment of the insert was isolated after BamHI
cleavage and cloned in the BamHI cleavage position from
pAJ that was first linearized with the enzyme BamHI.
10 Then the cDNA was prepared as the EcoRI/HindIII fragment
from pA7 and cloned in the vector pBIN-HYG. After
transformation by *Agrobacteria*, this was inserted for
infection of leaf segments of tobacco and potato.

15 Ten independently obtained transformands in
which the presence of the intact non-rearranged chimeric
gene was demonstrated using Southern blot analysis were
tested for modifications of amino acid and nitrogen
content. Besides this, amino acid synthesis,
photosynthesis rate and transportation were tested.

20 Example 5

Studies in the uptake of ^{14}C -labeled histidine in the yeast line AAP2

25 The yeast line JT16::AAP2, obtained in a
similar manner to Example 1, was grown in liquid medium
until the culture reached the logarithmic phase. After
centrifuging the culture, the cells were washed and taken
up in 10 mM tris/HCl pH 4.5, 2 mM MgCl_2 and 0.6M
sorbitol. Around 100 ml of the suspension was added to a
solution of 0.5 mM L-histidine plus 1 μCi ^{14}C -labeled L-
30 histidine in 100 μL of the same buffer. The uptake of

the labeled amino acid was measured according to the method described by von Cirillo (1989, Meth Enzymol 174: 617-622). The uptake of the labeled amino acid was compared in a competition experiment with that from different amino acids and analogues in tenfold excess. The relationships are shown in Fig. 5.

Table I

Inhibition of the amino acid transport in 22574d::PPP1-20 - yeast strains by protein modifying substances

		% of transport without inhibitor
10	0.1 mM DEPC (diethyl pyrocarbonate)	65
15	10 μ M CCCP (Carbonyl cyanide m-chlorophenylhydrazone)	<3
	10 μ M 2, 4 DNP (Dinitrophenol)	<3
	1 mM sodium arsenate	35
20	10 μ M antimycin A	29
	500 μ M PCMB (p-chloromercuribenzenesulfonic acid)	78

Table II
Competition by one, fourfold and tenfold excess of amino
acids and analogues in 22574d::PPP1-20 - yeast strain

Excess % remaining transport activity:		1 x	4 x	10 x
5	glutamic acid	64	27	30
	aspartic acid	78		27
	lysine	86		83
	histidine	81	79	58
10	arginine	85	88	74
	threonine	-	50	-
	L-proline	49	21	14
	D-proline	98		95
	3,4-di-OH proline	86		49
15	azetidine-			
	2-carboxylic acid	91		48
	OH-proline	81		45
	valine	-	77	47
	isoleucine	-	67	-
20	asparagine	64		57
	glutamine	-	27	-
	serine	53		18
	cysteine	-	21	-
	methionine	28		8
25	glycine	69		16
	alanine	55	29	23
	leucine	-		-
	tyrosine	-		-
	tryptophan	82	71	48
30	phenylalanine	45		16
	citrulline		44	
	gamma-aminobutyric acid		90	

Table III

Inhibition of the amino acid transports in JT16::AAP2 -
yeast strain by protein modifying substances

		<u>% of transport without inhibitor</u>
5	1 mM DEPC (Diethyl pyrocarbonate)	3.1 ± 1.6
	10 μM CCCP (Carbonyl cyanide m-chlorophenylhydrazine)	15.6 ± 2.1
10	10 μM 2,4 DNP (Dinitrophenol)	7.6 ± 1.6

Although the present invention has been described in relation to particular embodiments thereof, many other variations and modifications and other uses will become apparent to those skilled in the art. Therefore, the present invention is to be limited not by the specific disclosure herein, but only by the appended claims.
